摘 要 东昆仑夏日哈木铜镍矿床以赋存 110 万吨 Ni 金属成为全球镍床近二十年来最重要的发现之一,也是仅次于金川岩浆铜镍矿床的中国第二大铜镍矿床。矿区发育 5 个镁铁-超镁铁质岩体,目前仅 I 号镁铁-超镁铁岩体内发现了具有经济价值的超大矿体,110 万吨 Ni 金属均赋存 I 号岩体内;其他 4 个岩体中仅 II 号岩体发现了矿化,是多种构造体制叠加岩浆活动的结果。调查发现 II 号岩体的主要岩性是辉长岩,LA ICP-MS 锆石 U-Pb 测试获得 II 号岩体辉长岩的成岩年龄为 385.2 Ma,比 I 号岩体成岩成矿时代稍年轻,属于早泥盆世岩浆活动的产物。岩浆铜镍矿体多赋存于辉石岩与橄榄岩中,辉长岩内一般无经济价值的矿体存在。在夏日哈木矿区,辉长岩基本是含矿辉石岩及橄榄岩的围岩,辉长岩中所见的铜镍矿化也是后期岩浆活动贯入的表现。结合区域年代学综合分析认为,夏日哈木超大型岩浆铜镍硫化物矿床的形成,是早泥盆世早期岩浆活动于柴达木盆地边缘东昆仑造山带夏日哈木地区具体的成矿表现。目前所发现的 II 号岩体以辉长岩为主,不具备成镍矿良好条件,较难发现有经济价值的铜镍矿体。

Duan Jian-hua, Zhang Zhao-wei, Qi Chang-wei, Wang Ya-lei, Qian Bing, Zhang Jiang-wei, Mi Jia-ru, You Min-xin, Liu Yue-gao. Formation age of the gabbro in No. II intrusion at the Xiarihamu magmatic Ni-Cu sulfide deposit in the East Kunlun orogenic belt and its prospecting potential [J]. *Geology and Exploration*, 2017, 53(5): 0880-0888.

青海省夏日哈木岩浆铜镍硫化物矿床是近年来在东昆仑造山带发现的超大型矿床(李世金等, 2012; 张照伟等, 2015; Zhang *et al.*, 2017)。该矿床是仅次于甘肃省金川岩浆铜镍(铂族)硫化物矿床的中国第二大岩浆铜镍矿床,也是继 1996 年加拿大沃尔斯贝(Voisey's Bay)岩浆硫化物矿床发现二十年来全球镍矿最重要的发现(Li *et al.*, 2015; 张照伟等, 2017)。夏日哈木矿区共发育 5 个镁铁-超镁铁岩体,其 110 万吨的镍金属量仅赋存于其中一个镁铁-超镁铁质岩体(I 号岩体)内,其余 4 个岩体的含矿性尚不清楚。这 5 个镁铁-超镁铁质岩体之

间的关系,无疑直接影响到进一步的含矿性评价和勘探找矿方向。详细的野外调查和钻孔岩心编录发现,夏日哈木岩浆铜镍硫化物矿床的含矿岩体由橄榄岩、辉石岩及少量辉长岩组成,是多期次岩浆活动的产物(Li *et al.*, 2015)。镍矿体的形成仅与橄榄岩及辉石岩有关,辉长岩在含矿的超镁铁质岩侵位前后均有发育(冯惠彬等, 2015; 张照伟等, 2015; Zhang *et al.*, 2017)。夏日哈木矿区其他岩体的地质特征和找矿潜力有待进一步鉴别,其硫化物熔离机制与成矿过程、岩浆源区性质及构造背景也是制约深部找矿及含矿岩体形成过程的关键因素。本研究

拟从夏日哈木矿区 II 号岩体的空间形态和岩相分异入手,结合岩体的野外宏观特征、岩石地球化学特点和成矿时代,进一步探讨夏日哈木矿床 II 号岩体的成矿条件和勘查找矿方向,并评价其找矿潜力。初步总结可能产出的构造地质背景和成矿环境,对于深化岩浆铜镍硫化物矿床的形成机理认识,指导区域内类似岩体及矿床的发现与勘查具有重要意义。

1 区域地质背景

东昆仑夏日哈木岩浆铜镍硫化物矿床位于柴达木地块南缘东昆仑造山带中(图 1a)。以昆中区域性大断裂为界,东昆仑造山带又可进一步分为昆北和昆南造山带。昆北造山带中发育大量 391 ~ 410

Ma 的花岗岩,这些花岗岩侵入到前寒武纪变质基底及古生代火山沉积地层中,零星可见三叠纪沉积地层(图 1c)。在昆北造山带的东部,发现有 ~428 Ma 的榴辉岩,其他几处蛇绿混杂岩的年龄变化在 467 Ma ~ 518 Ma,并且这些蛇绿混杂岩的玄武质岩石表现出了典型的 MORB 特征(Meng *et al.* , 2013)。祁漫塔格早古生代岩浆弧以昆北断裂带为界与柴达木盆地接壤,昆南增生楔杂岩带则以昆南断裂带为界与巴喀喀拉造山带毗邻。东昆仑夏日哈木超大型岩浆铜镍硫化物矿床产于祁漫塔格早古生代岩浆弧内,临近黑山 - 那陵格勒断裂(图 1c)(Meng *et al.* , 2015; 尹利君等, 2016)。矿区出露地层主要为古元古代白沙河岩群,岩石类型为黑云斜长片麻岩、眼球

状混合片麻岩、大理岩、二云石英片岩等,原岩恢复为碎屑岩-碳酸盐岩-火山岩建造,经历了角闪岩相区域变质作用(李荣社等,2008;校培喜等,2014)。多个不同时代、不同规模的岩浆铜镍硫化物矿床发育于柴达木地块的北缘及其附近,如牛鼻子梁(柴达木西北缘 402 Ma)(钱兵等,2015)、亚曲

(东南祁连 441 Ma)、裕龙沟(东南祁连 443 Ma)(图 1b)(Zhang *et al.*, 2014)。但牛鼻子梁、亚曲及裕龙沟等岩体规模较小,至今尚未发现具有较大经济价值的矿体。

2 夏日哈木 II 号岩体地质特点

图 2 东昆仑夏日哈木岩浆铜镍硫化物矿区岩体地质分布略图(张照伟等,2015)

Fig.2 Map showing distribution of mafic-ultramafic intrusions from the Xiarihamu magmatic Ni-Cu deposit in the Eastern Kunlun orogenic belt (from Zhang *et al.*, 2015)

1 - Quaternary; 2 - Jinshuiou group; 3 - granite; 4 - diorite; 5 - eclogite; 6 - gabbro; 7 - websterite; 8 - gossan; 9 - Mg-peridotite; 10 - measured/inferred fault

东昆仑夏日哈木矿区 II 号岩体由地表出露的 3 个小露头组成(图 2,图 3a),地表基本被十几厘米至几十厘米厚的黄土覆盖(图 4a),东中西处岩体均呈透镜体状侵位于金水口群白沙河岩组地层中(图 3b)。西侧岩体呈东西向展布,走向约为 90°,长约 400m,宽约 200~350m,主要由中细粒辉长岩和中粗粒辉长岩组成,在中细粒辉长岩中可见零星呈斑杂状分布的镍黄铁矿。中部出露长 100m 左右、呈东西向展布的透镜体辉石岩,其北侧是钾长花岗岩及很小规模的榴辉岩(图 3a),辉石岩中可见零星磁黄铁矿化(图 4b)。东侧岩体呈北东东向展布,走

向约 75°,长约 550m,宽 50~240m,主要由辉长岩、辉石岩组成,露头辉石岩中局部见少量的镍黄铁矿,尤其在钻孔 ZK001 位置矿化现象最为明显(图 4f),且在 ZK001 钻孔深处见有少量辉石岩。在施工钻孔 ZK1101 中,岩心基本为古远古代金水口群地层和榴辉岩,并未见到辉石岩。

东昆仑夏日哈木矿区 II 号岩体铜镍矿化基本出现在辉石岩中,个别出现在辉长岩中。比如,钻孔 ZK001 位置附近的探槽中,单工程控制一矿体,矿体形态为透镜体,倾向约 245°,倾角约 60°,长为 40m,厚度为 5.05m,镍平均品位为 0.42%,多见镍的氧

化物(图4c、d),如镍华(图4e),少量新鲜岩石含有星点状镍黄铁矿(图4f),含矿岩性为辉石岩,辉石岩具有蛇纹石化。在钻孔 ZK001 的岩心中,根据矿化情况可推测一透镜体状矿化体,长为 40m,厚度为 3.15m,镍平均品位为 0.34%,含矿岩性为辉石岩。在钻孔 ZK301 岩心中,同样根据矿化推测可圈定一透镜状矿化体,总厚度为 9.98m,该矿体镍平均品位为 0.41%(图3c),但含矿岩性为辉长岩,辉长岩具有弱透闪石化和蛇纹石化,未见到辉石岩。

3 样品采集和测试方法

东昆仑夏日哈木矿区Ⅱ号岩体定年样品均采自地表及钻孔新鲜的辉长岩,其围岩为古元古界金水口群白沙河岩组(图3)。岩石呈灰黑色,块状构造,矿物成分主要是辉石与斜长石。

锆石挑选在河北省区域地质矿产调查研究所实验室利用标准重矿物分离技术分选完成。锆石制靶、反射光、阴极发光照相在西北大学大陆动力学国家重点实验室进行。经过双目镜下仔细挑选表面平整光洁且具不同长宽比例、不同柱锥面特征、不同颜色的锆石颗粒,再将这此锆石粘在双面胶上,用无色透明环氧树脂固定,待环氧树脂固化之后对其表面抛光至锆石中心。在原位分析之前,通过反射光和CL图像详细研究锆石的晶体形貌和内部结构特征,选择无明显裂痕及包裹体的锆石进行测年。锆石 U - Pb 定年在国土资源部岩浆作用成矿与找矿重点实验室完成,采用 193nm ArF 准分子(excimer) 激光器的 Geo Las200M 剥蚀系统, ICP - MS 为 Agilent7700,激光束斑直径 24μm,以 GJ - 1 为同位素监控标样,91500 为年龄标定标样, NIST610 为元素含量标样进行校正,普通铅校正依据实测²⁰⁴Pb 进行校正,所得锆石同位素比值和年龄数据应用 Glitter (ver4.0, Mac QuarieUniversity) 程序进行计算和处理,年龄计算及谐和图的绘制采用 Ludwig(2003) 编写的 Isoplot 程序完成。

4 测试结果及讨论

4.1 LA-ICP-MS 锆石 U-Pb 年龄

东昆仑夏日哈木矿区 II 号岩体辉长岩中锆石多呈柱状(长 $80 \sim 160 \mu\text{m}$),长宽比为 $1:1 \sim 2:1$,多数锆石内部可见清晰的震荡环带(图 5)。结合锆石的阴极发光(CL)、透反射特征,挑选透明的、无明显裂隙及包体的锆石开展锆石定年工作。所分析的 25 个有效点的(表 1) U 和 Th 含量分别为 $441 \times 10^{-6} \sim 5167 \times 10^{-6}$ 和 $141 \times 10^{-6} \sim 3799 \times 10^{-6}$, Th/U 比值

为 $0.20 \sim 1.93$,表明锆石均为岩浆成因,所测得年龄代表了岩石的结晶年龄。25 个数据锆石 $^{206}\text{Pb}/^{238}\text{U}$ 年龄主要分为两组,其中一组年龄集中在 $381.5 \sim 391.8 \text{Ma}$, $^{206}\text{Pb}/^{238}\text{U} - ^{207}\text{Pb}/^{235}\text{U}$ 谐和年龄为 $385.2 \pm 4.4 \text{Ma}$ (图 6a);另外一组年龄集中在 $423.3 \sim 425.6 \text{Ma}$, $^{206}\text{Pb}/^{238}\text{U} - ^{207}\text{Pb}/^{235}\text{U}$ 谐和年龄为 $429.7 \pm 4.7 \text{Ma}$ (图 6b)。两组年龄相差约 45Ma ,应为不同期岩浆活动的产物,这也与夏日哈木 I 号岩体中存在的两期辉长岩的年龄特征相似。

4.2 成岩构造背景

镁铁-超镁铁质侵入岩及其所含铜镍硫化物矿床的构造背景认识对于进一步指导区域找矿具有重要意义(Naldrett, 2009; Maier *et al.*, 2010; Li *et al.*, 2015; Song *et al.*, 2016; 张照伟等, 2016; Zhang *et al.*, 2017)。对夏日哈木铜镍矿区 II 号岩体中的辉长岩挑选锆石测试, 获得 385.2 ± 4.4 Ma 的谐和年龄, 该年龄基本代表了辉长岩的结晶年龄。Peng *et al.* (2016) 获得辉长岩的年龄为 424 ± 1 Ma, 说明辉长岩不是一次形成的, 可能是一期岩浆多次侵位的结果, 从钻孔岩心岩相接触关系也证明了这一点。

而对于夏日哈木 I 号岩体含矿辉石岩获得了 412.9 ± 1.8 Ma 和 410.9 ± 1.6 Ma 的谐和年龄(张照伟等, 2015), 辉长岩年龄 431 Ma (Li *et al.*, 2015); Song *et al.* (2016) 获得含矿辉石岩的年龄为 408 Ma。综合区域早泥盆世火山岩组合(玄武安山岩-安山岩-英安岩-流纹岩), 以及广泛出露的同时代花岗岩基, 多数学者认为该地区的早泥盆世处于碰撞后伸展阶段(祁生胜等, 2014; 张照伟等, 2016)。已有研究认为东昆仑岩浆弧的大约形成于 450 Ma ~ 430 Ma, 在昆北造山带的东部, 发现有形成于 428 Ma 的榴辉岩(Meng *et al.*, 2013; 杜玮等, 2015; 张照伟等,

2016),其他几处蛇绿混杂岩的年龄变化在 467 Ma ~ 518 Ma,并且这些蛇绿混杂岩的玄武质岩石具有典型的 MORB 特征(宋谢炎等,2009;谢燮等,2014;秦克章等,2014;芮会超等,2016)。夏日哈木超镁铁岩母岩浆表现了富集轻稀土、明显的负 Nb 异常,橄榄石中 Ca 亏损和高的 SiO₂ 含量,表现出了弧岩浆岩的特点(Naldrett,1999;2004;Li *et al.*, 2015;王亚磊等,2016;张照伟等,2016)。混有弧岩浆物质的原生岩浆,在上升过程中遭受地壳硫的混染,导致岩浆中的硫化物达到饱和,上升的岩浆中充满了不混溶的硫化物小液滴(张照伟等,2016)。尽管表现出了岛弧环境的地球化学信息,但并非一定就是岛弧背景,深部岩浆在上升过程中混染一些其他属性的地球化学信息不难理解。夏日哈木镁铁-超镁铁质侵入岩及铜镍硫化物矿床的形成,可能与柴达木盆地边缘裂解岩浆作用关系密切,是稳定陆块边缘岩浆活动的产物(张照伟等,2016)。

4.3 找矿潜力

夏日哈木矿区已发现 5 个镁铁-超镁铁岩体,但仅 I 号岩体发育了具有经济价值的超大型矿体,其他 4 个岩体目前尚未发现有价值的矿化线索(张照伟等,2016)。究其原因,这 5 个镁铁-超镁铁岩体并非同期同构造背景的产物,夏日哈木狭小区域内除含矿的镁铁-超镁铁岩之外,既有镁质橄榄岩,又有与深俯冲密切相关的榴辉岩(祁生胜等,2014),足见该区域地质构造背景的复杂性。夏日哈木 I 号岩体表现了多期次的成矿作用,是深部熔离-多期贯入成矿作用的具体表现,在其深部主要是岩浆来源的方向,存在进一步找矿空间与潜力。夏日哈木 II 号岩体,尽管已发现了少量的硫化物矿化,但岩体主体与旁边的榴辉岩是何关系尚不清楚,这也影响了对进一步找矿方向的判断。岩浆铜镍矿体基本都赋存在辉石岩及橄榄岩中,辉长岩充当了含矿辉石岩及橄榄岩的围岩,这从野外地质关系也可以说明(Li *et al.*, 2015;王猛等,2016)。夏日哈木 II 号岩体的辉长岩含有铜镍矿化,是深部熔离出的硫化物岩浆后期贯入的结果,规模小,经济意义不大。除夏日哈木矿区之外,在柴达木盆地西北缘发现了 402 Ma 牛鼻子梁含矿镁铁-超镁铁质侵入岩体(凌锦兰等,2014;钱兵等,2015;张照伟等,2015;刘建楠等,2016),在柴北缘也有类似侵入岩体的发现,并且伴有较好的铜镍矿化,只是成岩成矿时代尚未确定。这些岩体或者矿床的产出特点就是围绕柴达木克拉通周缘的造山带中,是稳定克拉通边缘破

坏岩浆活动的产物。

5 结论

(1) 东昆仑夏日哈木镁铁-超镁铁质岩体产出构造背景相对复杂,表现出多期次岩浆活动的特点,整体上可能是一次大的岩浆成矿事件,与柴达木盆地边缘裂解岩浆活动密切相关。

(2) 获得东昆仑夏日哈木矿区 II 号岩体的辉长岩结晶年龄为 385.2 Ma,属早泥盆世,但主体是辉长岩,辉长岩不是赋矿主岩,找矿潜力相对较差。

(3) 在柴达木地块南缘东昆仑造山带中,具明显岩相分带的铁质系列镁铁-超镁铁质岩体,是岩体含矿性评价的主要方向,富含橄榄石的辉石岩或橄榄岩才可能赋存有经济价值的铜镍矿体。

致谢 野外地质工作得到青海省地质调查局和青海省第五地质矿产勘查院领导及野外一线工作同志的支持、关心与帮助;论文评审专家给予了很好的建议和具体修改意见;在此一致深表感谢。

Abstract: The Xiarihamu Cu-Ni sulfide deposit, containing ~1.1 million tons of Ni metal, represents the most significant discovery in the history of global Ni exploration in the past two decades and is the second largest Ni deposit following the Jinchuan deposit in China. There are five mafic-ultramafic intrusions in the mining area. At present, all large-scale ore bodies with economic values have been discovered in the No. I intrusion, with 1.1 million tons of Ni metal. Among the other four intrusions, the mineralization was found only in the No. II intrusion, which resulted from superposition of magma activities of a variety of tectonic systems. In lithology, gabbro dominates the No. II intrusion. LA-ICP-MS zircon U-Pb analysis of the gabbro yielded a diagenetic age of 385.2 Ma. It is the product of the early Devonian magmatic activity, slightly younger than No. I intrusion. However, the magmatic Cu-Ni ores mostly exist in the Ol-pyroxite and peridotite, and there are generally no economically valuable ore bodies in the gabbro. In the Xiarihamu mining area, gabbro is largely the surrounding rock of peridotite and pyroxenite which hold Cu-Ni ores. The Cu-Ni mineralization observed in the gabbro is just a manifestation of late magmatic activity. Combined with the regional geochronology, it is concluded that the formation of the Xiarihamu super-large magmatic Cu-Ni sulfide deposit was associated with the early Devonian magmatic activity in the East Kunlun orogenic belt. The No. II mafic-ultramafic intrusion is dominated by gabbro, without good formation conditions of Cu-Ni ores, so it seems impossible to find Cu-Ni ore bodies with economic values in the No. II intrusion.

Key words: gabbro, zircon age, magmatic Ni-Cu sulfide deposit, prospecting potential, Xiarihamu, East Kunlun orogenic belt
